

THE DCC STRATEGY

My DCC strategy was built for only **ONE** goal:

PROP FIRM PAYOUTS

And since **2021**, I've been combining proven trading concepts to build the **PERFECT** strategy for trading with prop firms!

The trade frequency is optimized for passing challenges **FAST**.

The risk-to-reward ratio is ideal for hitting payouts **CONSISTENTLY**.

And the win rate is designed for **REPEATABLE** prop firm payouts instead of waiting months for one huge trade.

Forget swing trading. Forget scalping.

Forget learning vague concepts from random YouTube videos and learn an **ACTUAL**, data driven strategy like the ones hedge fund managers use.

My **DCC strategy** is a simple, **TECHNICAL** day trading strategy built around real market behavior, clear indicators and repeatable rules.

It completely changed my trading and helped me secure 200+ prop firm payouts & 7-figures in funding.

If you learn it, **BACKTEST** it and execute it properly, I genuinely believe it can change your trading too.

The entire strategy uses only three timeframes:

2H MAP → 1H BIAS → 5M ENTRY

STEP 1: THE DCC INDICATOR

I built the **BEST** indicator on TradingView based on the EXACT strategy that you'll learn in this PDF.

Over 400 traders already use it daily on their charts. ✓

Try it here free for 7 days:

<https://whop.com/dc-capital-7cc6/dcc-indicator/>

STEP 2: MAP ON THE 2H

Start on the 2H chart.

Map the latest swing high & low and use the 2H open price indicator to understand:

- Where price currently is
- Where price could react
- Whether there is enough space for your target
- Whether these zones could provide additional protection for your SL

The 2H tells you **WHERE** you are.

You're building the map before moving to the lower timeframes.

We're simply drawing three lines (daily open price, last swing high, and swing low)

2H timeframe:

STEP 3: BIAS ON THE 1H

Use the 9 EMA and 20 EMA to determine the market direction.

EMA = Exponential Moving Average indicator

For a **LONG** bias: **9 EMA above the 20 EMA**

For a **SHORT** bias: **9 EMA below the 20 EMA**

Avoid flat, messy or constantly crossing EMAs.

We want to see a clear separation between both EMAs.

1H timeframe:

Also, draw a horizontal line from the latest point on the 20 EMA.

The 1H tells you **WHICH DIRECTION** to trade.

You're no longer randomly deciding whether to buy or sell. The EMAs give you a **CLEAR** bias.

There is literally **ZERO** room for guessing or hesitation (exactly what a strategy is supposed to be)

1H timeframe:

STEP 4: ENTRY ON THE 5M

Once the 2H map and 1H bias are clear, move to the 5M chart.

This is where I use my **PFG** entry model:

PULL → FLIP → GO

Pull: Wait for a pullback in the opposite direction of our 1H bias

Flip: The 9 EMA has to flip over the 20 EMA in the direction of the 1H bias

Go: The 1H ADX must be above 25. For long trades, the 5M price must be above VWAP and the latest point of the 1H 20 EMA. For short trades, it must be below both.

(NOTE: You'll see a lot of these EMA flips on the M5 chart. Your goal is to first backtest the entire strategy and learn exactly which setups are worth taking and which ones aren't. Do NOT blindly enter a trade just because a flip happened on the M5 timeframe. You'll have more than enough entries, but you need to learn how to separate the high quality setups from the bad ones through backtesting first)

VWAP = Volume Weighted Average Price

ADX = Average Directional Index

VWAP shows the average price traded during the session, weighted by volume, helping you confirm whether buyers or sellers are currently in control.

ADX shows you how strong the current trend is.

The ADX value is 0-100, but you'll very rarely see it rise above 50-60

- 0-20 = weaker or messier trend
- Around 25 = a trend could be developing
- 25+40 = stronger trend
- Above 40 = very strong trend

I prefer taking setups when the 1H ADX is above 25.

But ADX is only a filter, a high ADX alone is **NEVER** a reason to enter.

EMAs show you the trend direction & bias.

VWAP provides additional confirmation & defense for our SL.

ADX tells you how strong the trend is.

5M timeframe:

Long Example:

- **Pair:** XAUUSD
- **2H:** Map swing high/low and daily open price line
- **2H:** No major 2H key levels interfering with our TP
- **2H:** The 2H daily open price line acts as a defense line for our SL (optional)
- **1H:** The 1H bias is bullish (9 EMA above the 20 EMA)
- **5M:** Price is above the horizontal line marking the 1H 20 EMA level (dotted purple line)
- **5M:** Price is above the VWAP line (dotted golden line)
- **5M:** The 1H ADX is at 47.4 (very strong trend)
- **5M:** A valid PFG entry forms
- **5M:** Stop loss: \$17 (1H ATR $\times$ 0.9)
- **5M:** Take profit: 1:1.5 RR

STEP 5: ATR BASED STOP LOSS

ATR = Average True Range indicator

ATR measures how much the market is currently moving.

When volatility is low, the ATR gives you a smaller stop loss range. When volatility is high, it gives you a wider range.

This helps prevent your stop loss from being:

- Too tight, causing normal price movement to stop you out
- Too wide, making you risk more than necessary

I figured out through years of split testing that the perfect stop loss distance for day trading can be calculated using:

1H ATR $\times$ 0.9

(My DCC indicator already shows the result of this formula, so no extra calculation needed)

This means your stop automatically adapts to forex, gold, futures, indices and different market conditions.

To give you a better feel for the ideal SL ranges for day trading, here are some general guidelines based on historical 1H ATR data for three different assets:

Volatility	EURUSD	GBPJPY	XAUUSD
Very low	1–5 pips	5–12 pips	\$1–\$5
Normal	6–10 pips	12–25 pips	\$5–\$12

High 10–15 pips 25–40 pips \$12–\$25

Extreme 15+ pips 40+ pips \$25+

Avoid “very low” and “extreme” conditions.

The DCC indicator shows the stop loss range ($1H\ ATR \times 0.9$) in the field labeled “SL”

DCC Strategy	
BIAS	SHORT
ADX	20.1
SL	0.00074

In the example above, for GBPUSD, the stop loss would be around 7.4 pips

DCC Strategy	
BIAS	SHORT
ADX	17.8
SL	14.386

In this example, for XAUUSD, the stop loss would be around \$14

Note: The indicator gives you a range not a fixed SL

With this model, you’re not using the same random stop distance on every instrument.

You’re not guessing where your stop loss should go.

You’re using real volatility data.

Again, it’s a repeatable system.

A REAL strategy, not vague concepts!

For the risk to reward ratio, aim for 1:1.5 RR – 1:2 RR.

(This is also something you should backtest first to determine which RR target works best for you)

Whenever there are no key levels interfering and there’s a strong trend, I like to aim for a 1:2 RR.

TRADE BREAKDOWN

Short Example:

- **Pair:** XAUUSD
- **2H:** Map swing high/low and daily open price line
- **2H:** No major 2H key levels interfering with our TP
- **1H:** The 1H bias is bearish (9 EMA below the 20 EMA)
- **5M:** Price is below the horizontal line marking the 1H 20 EMA level
- **5M:** Price is below the VWAP line
- **5M:** The 1H ADX is at 27 (strong trend)
- **5M:** A valid PFG entry forms
- **5M:** Stop loss: \$15 (1H ATR x 0.9)
- **5M:** Take Profit: Enough room to target a 1:2 RR

COMMON QUESTIONS

When do you trade?

6–9 AM UTC and 12–2 PM UTC.

However, the strategy works during all trading sessions. Backtest to find out which trading windows and days are most profitable for you.

Which markets does it work on?

Every market, including forex, futures and indices. I mainly trade EURUSD, XAUUSD, GBPUSD, GBPJPY and USDJPY.

How many trades do you take?

8–12 trades per week.

Do you hold trades overnight?

No. I always close my trades on the same day. The average trade duration is around 1–4 hours.

What win rate does the strategy have?

Usually around 55–60%, depending on the market and execution.

When do you avoid trading?

I avoid trading on NFP days, which usually fall on the first Friday of each month.

I also avoid the London session on Mondays and the New York session on Fridays because trends need time to develop. The market is either getting started for the week or preparing for the weekly close.

Do you trade during major news?

No. I avoid entering shortly before/after high impact news.

If you share this strategy with everyone, won't it eventually decay?

No. Strategies like this don't simply decay because more people learn them.

The DCC strategy isn't exploiting one tiny market inefficiency. It's built around fundamental market behavior that has existed for decades, including trends, momentum and indicators like EMAs, VWAP, ADX and ATR.

Extremely specific setups and vague concepts that random people with zero payouts teach on YouTube, like "take this exact entry on this exact candle at exactly 9:30 AM on this exact pair," decay.

But the DCC strategy doesn't depend on one specific time, pair, entry or tiny inefficiency. It's built around REAL market behavior that has worked for decades.

What makes the DCC indicator so powerful?

It combines real time daily bias, calculated stop loss size for every pair, automatic key level mapping, EMA flips, and the full DCC strategy checklist in one clean chart.

It's the exact indicator built around the DCC Strategy that I personally use and have used to get 200+ prop firm payouts and 7 figures in funding.

Is the indicator a signal tool?

No. It supports your analysis but does not automatically tell you when to trade.

Should I backtest the strategy first?

Yes, 100%. The DCC strategy is very technical and mostly mechanical, but that doesn't mean you should blindly enter every setup that meets the basic rules. Not every valid setup is an A+ setup.

You still need some discretion to recognize clean trends, avoid messy market conditions and understand which confirmations work best for you.

Backtest the strategy properly before using it on a prop firm challenge. Learn how it behaves across different instruments, sessions and market conditions.

The strategy works, but you still need to test it, understand it and learn how to execute it properly.

Never risk real money before building confidence through your own data. This is NOT a get rich quick scheme.

Why do you share this for free?

"A candle loses nothing by lighting another candle"

And I was tired of seeing prop firms make MILLIONS of dollars while most traders didn't, so I wanted to teach what I know actually works to beat them and build the DCC community around that mission.

THE FULL DCC STRATEGY

2H = KEY ZONES (Open price & swing high/low)

1H = BIAS (EMAs & ADX)

5M = ENTRY (PFG entry)

Stop Loss = 1H ATR x 0.9

Take Profit: 1:1.5 - 1:2 RR

The entire strategy in one line:

2H MAP → 1H BIAS → 5M PFG → ATR STOP → 1:1.5RR-1:2RR

This is literally the definition of a **REAL** trading strategy.

Based on years of testing.
No room for guessing or hesitation.
Simple, repeatable and technical.

It also combines the **most used indicators** among **hedge fund managers** and **professional institutional traders**, including EMAs, VWAP, ADX and ATR.

There is clear logic behind this strategy, which is exactly why it works so well and why I'm confident enough to say that my **DCC strategy** is the **MOST OPTIMIZED** strategy for beating prop firms.

This exact **strategy** helped me secure **200+ payouts**, **millions** in funding and **six figures** in profits.
